ABSTRACT

In this paper, we present madmom, an open-source audio processing and music information retrieval (MIR) library written in Python. madmom features a concise, NumPy-compatible, object oriented design with simple calling conventions and sensible default values for all parameters, facilitating fast prototyping of MIR applications. Prototypes can be seamlessly converted into callable processing pipelines through madmom’s concept of Processors, callable objects that run transparently on multiple cores. Processors can also be serialised, saved, and re-run to allow results to be easily reproduced anywhere.

Apart from low-level audio processing, madmom puts emphasis on musically meaningful features. Many of these incorporate machine learning techniques and madmom provides a module that implements some methods commonly used in MIR such as hidden Markov models and neural networks. Additionally, madmom comes with several state-of-the-art MIR algorithms for onset detection, beat, downbeat and meter tracking, tempo estimation, and chord recognition. These can easily be incorporated into bigger MIR systems or run as stand-alone programs.

1. INTRODUCTION

Music information retrieval (MIR) has become an emerging research area over the last 15 years. Especially audio-based MIR has become more and more important, since the amount of available audio data in the last years exploded beyond being manageable manually.

Most state-of-the-art audio-based MIR algorithms consist of two components: first, low-level features are extracted from the audio signal (feature extraction stage), and then the features are analysed (feature analysis stage) to retrieve the desired information. Most current MIR systems incorporate machine learning algorithms in the feature analysis stage, with neural networks currently being the most popular and successful ones [2, 3, 10, 18].

Numerous software libraries have been proposed over the years to facilitate research and development of applications in MIR. Some libraries concentrate on low-level feature extraction from audio signals, such as Marsyas [20], YAAFE [15] and openSMILE [8]. Others also include higher level feature extraction such as onset and beat detection as for example in the MIRtoolbox [14], Essentia [6] and LibROSA [16]. However, to our knowledge, there exist no library that also includes machine learning components (except Marsyas [20], which contains two classifiers), although machine learning components are crucial in current MIR applications.

Therefore, we propose madmom, a library that incorporates low-level feature extraction and high-level feature analysis based on machine learning methods. This allows the construction of the full processing chain within a single software framework, making it possible to build standalone programs without any dependency on other machine learning frameworks. Moreover, madmom comes with several state-of-the-art systems including their trained models, for example for onset detection [7, 18, 19], tempo estimation [3], beat [2, 10] and downbeat tracking [4, 13], and chord recognition [11, 12].

madmom is written in Python, which has become the language of choice for scientific computing for many people due to its free availability and its simplicity of use. The code is released under BSD license and pre-trained models are released under the CC BY-NC-SA 4.0 license.

1.1 Design and Functionality

1.1.1 Object-oriented programming

madmom follows an object-oriented programming (OOP) approach. We encapsulate everything in objects that are often designed as subclasses of NumPy’s ndarray, offering all array handling routines inherited from NumPy [21] with additional functionality. This compactly bundles data and meta-data (e.g. a Spectrogram and its frame rate) and simplifies meta-data handling for the user.

1.1.2 Rapid prototyping

madmom aims at minimising the turnaround time from a research idea to a software prototype. Thus, object instantiation is made as simple as possible: e.g., a Spectrogram object can be instantiated with a single line of code by only providing the path to an audio file. madmom automatically creates all objects in between using sensible default values.
1.1.3 Simple conversion into runnable programs

Once an audio processing algorithm is prototyped, the complete workflow should be easily transfomrtable into a runnable standalone program with a consistent calling interface. This is implemented using madmom’s concept of Processors.

1.1.4 Machine learning integration

We aim at a seamless integration of machine learning methods without the need of any third party modules. We limit ourselves to testing capabilities (applying pre-trained models), since it is impossible to keep up with newly emerging training methods in the various machine learning domains. Models that have been trained in an external library should be easily be convertible to an internal madmom model format.

1.1.5 State-of-the-art features

Many existing libraries provide a huge variety of low-level features, but few musically meaningful high-level features. madmom tries to close this gap by offering high-quality state-of-the-art feature extractors for onsets, beats, downbeats, chords, tempo, etc.

1.1.6 Reproducible research

In order to foster reproducible research, we want to be able to save and load the specific settings used to obtain the results for a certain experiment. In madmom this is implemented using Python’s own pickle functionality which allows to save an entire processing chain (including all settings) to a file.

1.1.7 Few dependencies

madmom is built on top of three excellent and wide-spread libraries: NumPy [21] provides all the array handling subroutines for madmom’s data classes. SciPy [9] provides optimised routines for the fast Fourier transform (FFT), linear algebra operations and sparse matrix representations. Finally, Cython [1] is used to speed up time critical parts of the library by automatically generating C code from a Python-like syntax and then compiling and linking it into extensions which can be transparently used from within Python. These libraries are the only installation and runtime dependencies of madmom besides the Python standard library itself, supported in version 2.7 as well as 3.3 and newer.

1.1.8 Multi-core capability

We designed madmom to be able to exploit the multi-core capabilities of modern computer architectures, by providing functionality to run several programs or Processors in parallel.

1.1.9 Extensive documentation

All source code files contain thorough documentation following the NumPy format. The complete API reference, instruction on how to build and install the library, as well as interactive Jupyter [17] notebooks can be found online at http://madmom.readthedocs.io. The documentation is built automatically with Sphinx.

1.1.10 Open development process

We follow an open development process and the source code and documentation of our project is publicly available on GitHub: http://github.com/CPJKU/madmom. To maintain high code quality, we use continuous integration testing via TravisCI, code quality tests via QuantifiedCode, and test coverage via Coveralls.

2. LIBRARY DESCRIPTION

In this section, we will describe the overall architecture of madmom, its packages as well as the provided standalone programs.

madmom’s main API is composed of classes, but much of the functionality is implemented as functions (in turn used internally by the classes). This way, madmom offers the ‘best of both worlds’: concise interfaces exposed through classes, and detailed access to functionality through functions. In general, the classes can be split in two different types: the so called Data classes and Processor classes.

Data classes represent data entities such as audio signals or spectrograms. They are implemented as subclasses of NumPy’s ndarray, and thus offer all array handling routines inherited directly from NumPy (e.g., transposing or saving the data to file in either binary or human readable format). These classes are enriched by additional attributes and expose additional functionality via methods.

Processor classes exclusively store information on how to process data, i.e. how to transform one data class into another (e.g., from an (audio-)Signal into a Spectrogram). In order to build chains of transformations, each data class has its corresponding processor class, which implements this transformation. This enables a simple and fast conversion of algorithm prototypes to callable processing pipelines.

2.1 Standalone Programs

madmom comes with a set of standalone programs, covering many areas of MIR. The outstanding results in Table 1 highlight the state-of-the-art features madmom provides.

Table 1. Ranks of the programs included in madmom for the MIREX evaluations, results aggregated over all years (2006-2016).
